

---

table 53: adjusted frequencies using the EC method  
CZ-unmixed gender

---

the table presents the adjusted frequencies using the *expression count method* developed by C.G. Turner (1985), calculated for the different assemblages defined for the analyses (a summary of the definition of groups is found in table 52)

tables are structured as follows:

- the first column indicates the sample size of the unit (**N**)
- the second indicates the observed sample size for the variable (**n**)
- the following columns are variable and dependant on the graduations of the traits observed, these are **adjusted frequencies**, calculated with the following formula:

$$X \text{ freq\_aj} = \text{freq} * \text{coefficient}1/X$$

- the next to last column gives the **sum of the adjusted frequencies**:

$$\sum \text{freq\_aj}$$

- the last column is the **value of the expression count**, calculated as follows:

$$\text{E.C.} = \sum \text{freq\_aj} * n/N$$

a table in italics indicates that the expressions of the variable within the populations are constant

grayed data indicate that the sample size for the population is insufficient (<5) to be included in the analyses
